## CCSBT－ERS／2203／04

## Summaries from the 2021 ERSWG Data Exchange

## Introduction

This paper presents summaries from the data provided for the ERSWG Data Exchange（EDE）． ERSWG 10 tasked the Secretariat with providing summaries of the exchanged data to ERSWG meetings，noting that the data would be aggregated over Members．The summaries would include at least observed and actual effort，observer coverage rate，observed mortalities and estimated total mortalities．Summaries would be provided separately for CCSBT statistical areas and species／species groups．The tables and figures presented in this paper are mainly an update of those presented in paper CCSBT－ERS／1905／04 at ERSWG 13.

The EDE commenced in 2013 with data provided for 2010 to 2012．Data have been submitted yearly since then and now includes information up to and including 2020．The summaries in this paper are for all data held by the Secretariat and include an additional three years data to the summary presented at ERSWG 13，plus some revisions to previously included data．Table 2 summarises the data provided by Members．South Africa has not provided data for 2019 and 2020. Korea provided revised data for 2010 and 2012－2017 in February 2022．It did not revise its 2011 data since it has no observer data to provide for that year．Korea also had no observer coverage for 2020，so it has not provided any observed catch data for 2020．Australia indicated that it would provide revised historical data in January 2022 but has not done so at the time of writing．

At ERSWG 13 Members agreed to a new EDE template with data provided at higher spatial and temporal resolution and agreed to provide data from at least 2019 in the new format．Table 1 below shows the years for which Members have provided EDE data in the new format．

Table 1－Years for which CCSBT Members have provided ERSWG Data Exchange（EDE）data in the new format with a $5 \times 5$ resolution ${ }^{l}$ ．

| Year | AU | ID | JP | KR | NZ | TW |

[^0]CCSBT Circular \#2019/023 provided a letter from Japan dated 28 March 2019, which stated: "In December, 2018, National Research Institute of Far Seas Fisheries (NRIFS) informed FAJ that they have found suspicious and/or inconsistent descriptions on seabird and other species data in certain observer reports recorded on Japanese large-scale longline vessels fishing for southern bluefin tuna in high-latitude areas of the southern hemisphere. Upon this, FAJ started its investigation into such observer reports.". Subsequently, in May 2019, Japan provided revised 2016 and 2017 observer data for the EDE. This reduced Japan's reported 2017 observer coverage by over one million hooks, which is over $50 \%$.

Table 2 - Summary of ERSWG Data Exchange data by Members. The European Union had no reported SBT catch from 2013-2020 and therefore had no data to submit for those years. Indonesia has provided data for all years but has not been able to provide estimates of total fishing effort for 2010-2015. Furthermore, Indonesia has provided data for its entire longline fleet, not just sets where SBT were caught or targeted, and has not provided information on its usage of mitigation measures with its data. Therefore, Indonesia's data are not compatible with that provided by the other Members.

|  | Australia | EU | Indonesia | Japan | Korea | New Zealand | South Africa | Taiwan |

The specifications of the EDE provide a template for the provision of data. The submissions received from Members followed the template but there were substantial differences in the level of species detail provided. Some Members ${ }^{2}$ provided species specific data, while others ${ }^{3}$ used the "species/species groups" defined within the EDE as the 'minimum taxonomic level at which information should be reported'. The summaries in this document are aggregated over Members, so these "species/species groups" are the finest common level of detail that can be presented (the groups are shown in Table 3).

[^1]Table 3 - Minimum taxonomic level at which information should be reported for the ERS Data Exchange (providing that such
taxonomic detail is available).

| Species/Species Group | Comments |
| ---: | :--- |
| Sharks |  |
| Blue Shark |  |
| Shortfin Mako Shark |  |
| Porbeagle |  |
| Other sharks |  |
| Turtles | For sea turtles, the number of species is small (approximately 7), so it is feasible to report data by stratum for each species. |
| Species specific | Data should be provided separately for each species |
| Seabirds | For seabirds, there are a large number of species and it is often difficult to separately identify species by pictures only. <br> Leporting of seabird data by species would contain identification errors. |
| Large albatrosses | Including: Wandering, Tristan, New Zealand, Antipodean, Southern Royal, and Northern Royal <br> albatrosses |
| Other albatrosses | Including: Sooty and Light-mantled <br> Giant petrels |
| Other seabirds <br> Chatham: and White-capped | Including: White-chinned petrel, Grey petrel, Flesh-footed shearwater etc. |
| Including: Skua etc. |  |

For reference, the CCSBT Statistical Areas are shown in Figure 1 below.

Effort Summaries
As per the rules of the EDE, the fishing effort provided by Members is defined as being effort by CCSBT authorised vessels for shots/sets where SBT was either targeted or caught.

Attachment A shows observer coverage by flag, gear, fleet, year and CCSBT statistical area. The final column, representativeness, is the proportion of statistical areas fished that reached the target of $10 \%$ observer coverage as per the SMMTG Recommendations. There are only two fleets that maintained a representativeness of $100 \%$ for all years fished, these being the charter fleets for New Zealand and South Africa.

Longline effort summaries are shown in Table 4 and as maps in Attachment B. On the maps the circle area is proportional to the total number of hooks set in that area, with the yellow slice representing the proportion of hooks that were observed. The scale is the same across years. Note that for 2013, area 6 effort does not include New Zealand (NZ) domestic fleet effort. NZ did not submit figures for total or observed effort for the domestic fleet in that area and year and advised that operational issues resulted in very low observer coverage of the domestic fleet ( $<1 \%$ ). The Indonesian domestic fleet is also not included in the tables maps as Indonesia has not been able to
provide estimates of total effort for 2010-2016, and where it has provided effort data it is for the entire longline fleet and not effort by CCSBT authorised vessels for shots/sets where SBT was either targeted or caught.

Over the 11-year period longline observer coverage was on average $12.7 \%$ of total effort, but coverage varied considerably by area and year. The observer coverage from 2012 to 2016 was over $12 \%$ for each year, an improvement on 2010 and 2011 where the average coverage was less than $10 \%$. Japan's observer coverage for 2017 and 2018 was less than $10 \%$ due to it removing a substantial amount of its observer data. Observer coverage for 2020 was affected by the COVID-19 pandemic with most Members not achieving $10 \%$ coverage, and Korea having placed no observers for that year. The observer coverage for areas from $40^{\circ} \mathrm{S}$ to $60^{\circ} \mathrm{S}$, where the most birds are caught, is noticeably lower in 2020.

Table 4 - Longline effort by year and statistical area, with observer coverage

| Year | Statistical area | Total effort (1000s of hooks) | Observed effort (1000s of hooks) | Observer coverage |
| :---: | :---: | :---: | :---: | :---: |

| Total |  | 407,440 | 51,517 | 12.6\% |

Table 5 shows the percentage observer coverage of longline effort for areas that are considered to be important for seabirds. Statistical areas 2 and 8 have been combined, as have areas 5 and 6 .

Table 5 - Longline observer coverage by year for areas that are important for seabirds.

|  | Year |  |  |  |  |  |  |  |  |  |  |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: |
| Statistical Area(s) | 2010 | 2011 | 2012 | 2013 | 2014 | 2015 | 2016 | 2017 | 2018 | 2019 | 2020 |
| 2/8 | 13\% | 9\% | 15\% | 17\% | 13\% | 9\% | 12\% | 10\% | 15\% | 21\% | 12\% |
| 5/6 | 24\% | 17\% | 17\% | 24\% | 35\% | 30\% | 14\% | 20\% | 9\% | 11\% | 11\% |
| 7 | 0\% | 7\% | 4\% | 7\% | 15\% | 16\% | 24\% | 11\% | 2\% | 24\% | 5\% |
| 9 | 6\% | 10\% | 14\% | 10\% | 7\% | 15\% | 20\% | 5\% | 12\% | 22\% | 9\% |

Purse seine effort summaries are shown in Table 6 and as maps in Attachment C. On the maps the circle area is proportional to the total number of sets in that area, with the yellow slice representing the proportion of sets that were observed. Observer coverage averages $15.4 \%$ over the 11 -year period but was less than $10 \%$ in 2015. Some statistical areas with a small number of sets for the year had no observer coverage.

Table 6 - Purse seine effort by year and statistical area, with observer coverage.

| Year | Statistical area | $\begin{gathered} \text { Total effort } \\ \text { (sets) } \\ \hline \end{gathered}$ | Observed effort (sets) | Observer coverage |

| Total |  | 1,433 | 221 | 15.4\% |

## Observed Mortality Summaries

Table 7 shows observed mortalities by year, statistical area, and species/species group for the SBT longline fishery, while attachments D and E map the distribution of observed mortalities for seabirds and sharks respectively. For the pie maps, the area of the pie is proportional to the total number of observed mortalities, with pie slices representing the proportion of each species/species group. The scale is the same across years.

Table 7 - Observed mortalities for the SBT longline fishery by year, statistical area and species/species group

| Year | Statistical area | Blue shark | Shortfin mako shark | Porbeagle | Other sharks | Turtles | Large albatross | Dark coloured albatross | Other albatross | Giant petrels | Other seabirds |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: |

The number of observed bird mortalities by area varies considerably from year to year. 2017 and 2020 have the lowest observed bird mortalities in the 11-year period but this may be due to the lower amount of observer data available for those years. Note that a large proportion of mortalities are in the 'other albatross' and 'other seabirds' categories, some of which are unidentified seabirds that may belong in a different category.

The number of observed shark mortalities by area also varies considerably from year to year. Note that a large proportion of shark catch was not given a life status, see the charts and discussion on catch rates (and Attachment F). Some Members have only been including discarded mortalities in their EDE figures, and have not included retained catch, while other Members have included both. This is mainly an issue for data provided in the older EDE format (data provided for calendar years prior to 2017) since the new format specifically includes retained catches, although some Members have not included retained catch when calculating mortality rates. Korea provided revised historical data in the new EDE format to address this issue. Australia has indicated that it will provide revised historical data but has not yet provided it.

Table 8 shows observed mortalities for all seabirds combined, by year and statistical area. $86 \%$ of all observed bird mortalities occurred in areas 7,8 , and 9 .

## Observed Catch and Mortality Rate Summaries

Attachment F shows observed catch rates (numbers caught per thousand hooks) by year for each species group. The bars are divided by fate; red for observed mortalities, green for observed live releases, and grey for 'unknown life status' (for each species Members provide total numbers caught, the number of individuals observed to be dead, and the number observed to be released alive. The 'unknown life status' number is the calculated discrepancy between 'total caught' ('observed dead' + 'observed released alive')).
Attachment G shows observed catch rates by species group, year, and statistical area.

Attachments H and I map mortality rates for seabirds and sharks respectively, while attachments J and K map capture rates for seabirds and sharks. The areas of the pies are proportional to the total mortality rate (H and I) or capture rate ( J and K ) of all species combined, with pie slices representing the proportion of each species/species group. The scale is the same across years for each map series. Note that in attachments I and K the data for statistical area 15 have been removed for 2014 and 2017. These points had extremely high capture and mortality rates for shortfin mako and blue shark but was for less than 10000 observed hooks.

Observed catch and mortality rates for seabirds are similar due to the low proportion of live releases. The overall bird rates appear to be the lowest in 2020 but this may be due to lower observer coverage in the areas where the most seabirds are caught.

Observed shark mortality rates appear to be relatively low in 2020 but as with birds this may be affected by the lower observer coverage in certain areas.

## Summaries of the Estimated Total Number of Mortalities

The older ERSWG templates include a column for the estimated total number of mortalities per year/stratum. For data submitted using the older templates this particular column was provided for all years by four of the seven Members whose data are used in this report, not provided for any years by one Member, and partly provided for recent years by two Members. Where the estimated total number of mortalities was provided, Members mostly used a simple scaling of the observed number of mortalities according to the observer coverage of the stratum and rounded fractions down to the next integer (even for fractions greater than 0.5 ). For data provided in the older formats, the estimated total number of mortalities for the three Members that did not provide the column were calculated by scaling the number of observed mortalities by the observer coverage of the stratum and rounding down to the nearest whole number, to be consistent with the data provided by the other Members.

At ERSWG 13, when Members agreed on a new EDE template, Members also agreed that the Secretariat would calculate the estimated total number of mortalities for data provided in the new format, using the following method:
"raised mortalities would be estimated by applying a simple scaling ratio of observed mortalities and observed effort at the Statistical Area by fleet and year strata to the total effort. For finer scale estimates (e.g. $5 \times 5$ degree cell by quarter), the ratio calculated for the Statistical Area by fleet and year strata would be applied at the finer scale."

The Secretariat has used this method for all data provided in the new EDE template (see Table 1). Due to the method of using a raising ratio by year and statistical area on finer scale data it does not seem appropriate to consider estimated total mortalities at the finer scale, so they are not presented in this paper.

Note that due to the simple, non-model based, approach used to estimate the total number of mortalities, and the low level of observer coverage in many strata which results in a high scaling factor, the numbers should be treated with caution.

Table 10 shows estimated total mortalities by year, statistical area, and species/species group for the SBT longline fishery, while attachments L and M map the distribution of estimated total mortalities for seabirds and sharks respectively. As with observed mortalities, the areas of the pies are proportional to the total number of estimated mortalities, with pie slices representing the proportion of each species/species group. The scale is the same across years.

The distribution of total estimated bird mortalities by area is similar to the distribution of observed mortalities, and also varies considerably from year to year. There are also relatively large numbers of seabirds in the 'other albatross' and 'other seabirds' categories, some of which are unidentified seabirds that may belong in a different category.

The distribution of total estimated shark mortalities by area is also quite similar to the distribution of observed shark mortalities and also varies considerably from year to year, so the same comment
applies that it is difficult to see clear visual patterns other than blue shark being caught in much larger numbers than any other shark species.

Table 10 - Estimated total mortalities for the SBT longline fishery by year, statistical area, and species/species group

Table 11 shows the estimated total mortalities for all seabirds combined. As with Table 8 regarding observed mortalities, areas 7,8 , and 9 have the highest total mortalities, but area 4 also has appreciable mortalities. When comparing the mortalities between years, it is important to remember that no mortality data is available for South Africa in 2019 or 2020 and for Korea in 2020.

Table 11 - Estimated total mortalities for the SBT longline fishery for all seabirds combined by year and statistical area

Table 12 shows estimated total mortalities by year, statistical area, and species/species group for the SBT purse seine fishery. There were no observed mortalities, so the total estimated mortalities are zero for this fishery.

## Summaries of Observed Effort with Specific Mitigation Measures

After ERSWG11, Members were required to provide the proportion of effort with specific mitigation measures. These have been aggregated over all fleets and statistical areas and are summarised in Table 13 below for 2014 to 2020 (these data are not available for most Members for earlier years). The column for 'Mix of 2 measures includes effort where two measures were used at all times but switched from night setting/tori pole to tori pole/branch lines after dawn. The highest proportion of effort with a single or no mitigation measures being used occurred in 2016 and 2019, with over $30 \%$ of the effort in these years involving a single or no mitigation measures.

Table 13 - Proportions of observed effort with specific mitigation measures by year.

|  | Tori pole + <br> Night <br> setting | Tori pole + <br> weighted <br> branchline | Night <br> setting + <br> weighted <br> branchline | Tori pole + <br> night setting + <br> weighted <br> branchline | Tori <br> pole | Night <br> setting | Weighted <br> branchline | None | Single <br> measure <br> (unspecified) | Mix of 2 <br> measures |

Prepared by the Secretariat

Observer coverage (observed hooks / total hooks or observed sets / total sets expressed as a percent) by flag, gear, fleet, year and CCSBT statistical area. Representativeness is the proportion of statistical areas fished that reached the target of 10\% observer coverage as per the SMMTG Recommendations. Cells shaded in grey are strata with low effort (<25,000 hooks for longline and <5 sets for purse seine).

Longline SBT effort showing observer coverage (yellow)

Purse seine SBT effort, showing observer coverage (yellow)
Attachment C

Observed bird mortalities for the SBT longline fishery

Observed shark mortalities for the SBT longline fishery

Observed capture rates (numbers per 1000 hooks) with proportions of observed mortalities (red), observed live releases (green) and unspecified life status (grey) for the SBT longline fishery by year and species/species group

Attachment G

Observed catch rates for the SBT longline fishery by year, statistical area and species/species group

Observed bird mortality rates for the SBT longline fishery

Observed shark mortality rates for the SBT longline fishery

## Observed bird capture rates for the SBT longline fishery

## Observed shark capture rates for the SBT longline fishery

## Estimated total bird mortalities for the SBT longline fishery

## Estimated total shark mortalities for the SBT longline fishery

[^0]:    ${ }^{1}$ The European Union and South Africa are not included in this table．The EU does not target SBT and it has reported no catch of SBT and therefore it has no related ERS data to report．South Africa has not provided any EDE data in the new format nor any EDE data for 2019 and 2020.

[^1]:    ${ }^{2}$ Australia, Indonesia, Korea, New Zealand, South Africa, Taiwan.
    ${ }^{3}$ Japan
