# BYCATCH OF THE EUROPEAN PURSE-SEINE TUNA FISHERY IN THE ATLANTIC OCEAN FOR THE PERIOD 2010-2016 

J. Ruiz Gondra*1, J. Lopez ${ }^{2}$, F.J. Abascal ${ }^{3}$, P.J. Pascual Alayon ${ }^{3}$, M.J. Amandè ${ }^{4}$, P. Bach ${ }^{6}$, P. Cauquil ${ }^{5}$, H. Murua ${ }^{2}$, M.L. Ramos Alonso ${ }^{3}$, P.S. Sabarros ${ }^{5}$<br>SUMMARY

This paper presents an update for the period 2010-2016 of the bycatch estimations for the European tuna purse seine fishery operating in the Atlantic Ocean. Bycatch data were collected by observers onboard. Observer coverage increased progressively from 15 trips in 2010, to 114 and 107 trips in 2015 and 2016 respectively. Bycatch data, as collected by the observers, were stratified by quarter and fishing mode (free school and floating object sets). The ratio of total to observed catches of the target species (skipjack, bigeye and yellowfin tunas) in each stratum was then used as raising factor. The average of the annual total bycatch estimated for the studied period was $9,515 \mathrm{t}$. Tunas (neritic tunas and small size tunas) represent the major part of the bycatch, followed by fin fish, sharks, billfishes, rays and turtles.

## RÉSUMÉ

Cet article présente une mise à jour concernant la période 2010-2016 des estimations des prises accessoires de la pêcherie des senneurs thoniers de l'Union européenne opérant dans l'océan Atlantique. Les données sur les prises accessoires ont été recueillies par des observateurs à bord. La couverture par des observateurs a progressivement augmenté, passant de 15 sorties en 2010 à 114 sorties en 2015 et 107 sorties en 2016. Les données sur les prises accessoires, recueillies par les observateurs, ont été stratifiées par trimestre et par mode de pêche (sur bancs libres et sous objets flottants). Le ratio entre les prises totales et les prises observées des espèces cibles (listao, thon obèse et albacore) dans chaque strate a ensuite été utilisé comme facteur d'extrapolation La moyenne des prises accessoires annuelles estimées pour la période étudiée s'élevait à 9.515 t. Les thonidés (thons néritiques et thons de petite taille) représentent la majeure partie des prises accessoires, suivis des poissons à nageoires, des requins, des istiophoridés, des raies et des tortues.

#### Abstract

RESUMEN En este documento se presenta una actualización para el periodo 2010-2016 de las estimaciones de captura fortuita de la pesquería de cerco atunera europea que opera en el océano Atlántico. Los datos de captura fortuita fueron recopilados por observadores a bordo. La cobertura de observadores se incrementó progresivamente pasando de 15 mareas en 2010 a 114 y 107 mareas en 2015 y 2016 respectivamente. Los datos de captura fortuita, tal y como fueron recopilados por los observadores, se estratificaron por trimestre y modo de pesca (lance sobre banco libre y sobre objeto flotante). A continuación, se utilizó como factor de extrapolación la ratio de capturas totales y capturas observadas de especies objetivo (listado, patudo y rabil) en cada estrato. El promedio de captura fortuita total anual estimada para el periodo estudiado se situó en 9.515 t. Los túnidos (túnidos neríticos y túnidos de talla pequeña) representan la mayor parte de la captura fortuita, seguidos por los peces de aleta, tiburones, marlines, rayas y tortugas.

## KEYWORDS

Bycatch, purse seining, Atlantic Ocean

## Introduction

All fishing methods aim to extract wild species from the aquatic environment. When fishing, other accessory species, also known as "bycatch" are caught in addition to the target species. The bycatch varies according to various factors, like fishing techniques, or market factors (Kelleher, 2005). On the other hand, the dynamics of populations, such as seasonal migrations, high recruit's concentrations in certain areas or spawning in certain zones and times, can change the amount of bycatch seasonally and geographically (Lart et al., 2002). Obtaining quantitative and qualitative information (composition by species) and its evolution over a period is fundamental for a better management of resources (Lart et al., 2002), not only from the point of view of the management of commercial stocks but also from the point of view of ecosystem management.

Regarding the tropical tuna purse seine fishery, several papers and documents in the past have provided information on bycatches and discards (Peatman et al., 2017; Hall and Roman, 2013; Amandè et al., 2008), some of them referring specifically to the European purse seine fishery operating in the Atlantic Ocean (Amandè et al., 2010; Amandè et al., 2011).

The main objective of this paper is to present an update on the bycatch estimations for European tuna purse seine fishery operating in the Atlantic Ocean, with the aim of understanding better the impact of the fisheries on the environment. For this purpose, bycatch was defined as the discard of target species (skipjack, yellowfin and bigeye tuna) plus the catch of non-target species, whatever the fate is.

## 1. Method

### 1.1. Data

The data collected by independent observers during fishing operations are commonly used to complement other data, such as those from port sampling or skippers' logbooks. For some types of data, such as bycatch and discards, observer programs can be the most reliable, and sometimes the only source of information available. Observer programs are becoming an increasingly important tool to monitor tropical tuna fisheries. Under the ICCAT regulation, there is a recommendation of $5 \%$ coverage for large fishing vessels (ICCAT, 2010). Since 2003, Spain and France have been conducting a coordinated observer program as part of the Spanish and French National Programs for the Data Collection in the Fisheries sector established according to the European Regulations (Commission Regulation (EC) No. 665/2008). Since 2012, monitoring requirement increases to $100 \%$ for purse seiners during a two-month prohibition on FAD fishing in an area off western Africa (ICCAT Rec. 11-01; ICCAT Rec. 15-01). In addition, observer coverage increased significantly during recent years through private contracts between industry and scientific institutes. Data for the analyses has been collected under all these different monitoring programs.

Observer coverage increased progressively from 15 trips in 2010 to 114 and 107 trips in 2015 and 2016 respectively. Thus, the coverage of data varies significantly between the first years of the series, where only the DCF sampling existed, and the last ones where, through the different observer programs, the number of observed fishing operations is above 2,000 (Figure 1). In terms of production, observed coverage is between $8-9 \%$ in the first years of the study period, and around $50-60 \%$ in the most recent years (Table 1).

### 1.2. Analysis and raising

Bycatch was assumed to be linearly correlated with production (Amandè et al., 2010), understood as the total landings of target tuna species (skipjack, yellowfin and bigeye tuna). Thus, the total production of the EU purse seine fleet was used as the ratio estimator for the raising of the total bycatch in weight. Extrapolation was done yearly, and stratified by quarter and fishing type; sets on floating objects (FOB) and free school sets (FSC).

## 2. Results

The average of the annual total bycatch estimated for the studied period was $9,515 \mathrm{t}$, with a minimum of $6,734 \mathrm{t}$ in 2011 and a maximum of 13,204 t in 2013 (Table 2; Figure 2). Figure 3 shows the same estimates by quarter. In relation to the fishing mode, most of the bycatch occurs in FOB sets, representing more than $80 \%$ of the total annual bycatch in the whole period, and reaching $95 \%$ in 2014 (Table 4). Tunas (neritic tunas and discards of major tunas) represent the major part of the bycatch, followed by fin fish, sharks, billfishes, rays, and turtles.

### 2.1. Tunas

Tunas constitute the bulk of the bycatch both in FOB and FSC, between $67 \%-89 \%$ and between $36 \%-88 \%$ respectively (Table 4). In terms of species composition, species of the genera Auxis and Euthynnus are the predominant, both in FOB and FSC. Regarding target species, skipjack is the main discarded tuna in FOB sets (around $20 \%$ of the total tuna bycatch). In the case of FSC, where the tuna bycatch is much lower, it is not so clear which is the predominant species. However, the importance of Thunnus alalunga is significant compared to that on FOB sets (figure 4).

### 2.2. Fin-fish

After tunas, "other fin fish" is the group that most contribute to the total bycatch, mainly due to FOB sets (Table 4). In terms of species composition, the number of fin fish species present within the observed fishing operations exceeds 60 in FOB sets, and 40 FSC sets. However, there are a few predominant species in both cases (Figure 4). Acanthocybium solandri, Coryphaena hippurus, Elagatis bipinnulata, Canthidermis maculata and Caranx crysos are the main caught species. However, this predominance is less evident in FSC sets, where Mola mola has a significant importance.

### 2.3. Shark

163 whale sharks (Rhyncodon typus) catch events were reported by observers during the whole studied period (Table 6). These events where particularly reported in the Cape Lopez area. Whale sharks escaped from the net or were discarded alive almost always before the retrieval of the net. Subsequently shark group bycatch estimation did not include whale sharks.

In total terms, the estimated shark bycatch quantity is similar in FSC and FOB, and the annual average bycatch for the study period is around 245 t per year. However, the variability between years is higher in FSC (Table 2). In terms of the species composition, Carcharhinus falciformis is the main species. In the case of the FOB sets, along with sharks of the family Sphyrnidae (mainly Sphyrna lewini and Sphyrna zygaena). In FSC sets, Prionace glauca becomes more important (Figure 4).

### 2.4. Billfish

Billfish catches accounted for around $2 \%$ and $6 \%$ of the total bycatch in FOB and FSC sets respectively (Table 4). In terms of species composition, Makaira nigricans is the predominant species in FOB sets, while Istiophorus albicans is the main species in FSC sets (Figure 4).

### 2.5. Turtles

1,228 turtle catch events were reported by observers during the whole studied period, 925 in FOB sets and 303 in FSC sets (Table 7). $99,1 \%$ were released alive. In terms of species composition, Lepidochelys olivacea was the main caught species followed by Caretta caretta. Regarding spatial distribution, most of the catches (68\%) were observed in Cape Lopez.

### 2.6. Cetaceans

202 cetacean catch events were reported by observers during the whole studied period (Table 7). All of them were discarded alive, and were discarded almost always before the retrieval of the net.

## 3. Acknowledgments

Authors would like to acknowledge organizations responsible of the data collection funding: Data presented in this paper where collected in the frame of the EU Data Collection Framework, the French OCUP "Observateur Commun Unique et Permanent" supported by French purse seine companies (Orthongel, professional organization of the French tropical tuna purse seine fishery), and the Spanish "Best practices monitoring program" supported by Spanish purse seine associations (ANABAC and OPAGAC).
